Review

Infrastructure, programs, and policies to increase bicycling: An international review

ABSTRACT

Objectives. To assess existing research on the effects of various interventions on levels of bicycling. Interventions include infrastructure (e.g., bike lanes and parking), integration with public transport, education and marketing programs, bicycle access programs, and legal issues.

Methods. A comprehensive search of peer-reviewed and non-reviewed research identified 139 studies. Study methodologies varied considerably in type and quality, with few meeting rigorous standards. Secondary data were gathered for 14 case study cities that adopted multiple interventions.

Results. Many studies show positive associations between specific interventions and levels of bicycling. The 14 case studies show that almost all cities adopting comprehensive packages of interventions experienced large increases in the number of bicycle trips and share of people bicycling.

Conclusions. Most of the evidence examined in this review supports the crucial role of public policy in encouraging bicycling. Substantial increases in bicycling require an integrated package of many different, complementary interventions, including infrastructure provision and pro-bicycle programs, supportive land use planning, and restrictions on car use.

Introduction

Bicycling is healthy. That is the conclusion of an increasing number of scientific studies assessing the impacts of bicycling on levels of physical activity, obesity rates, cardiovascular health, and morbidity (Anderson et al., 2000; Bassett et al., 2008; Bauman et al., 2008; BMA, 1992; Cavill et al., 2006; Dora and Phillips, 2000; Gordon-Larsen et al., 2009; Hamer and Chida, 2008; Hillman, 1993; Huy et al., 2008; Matthews et al., 2007; Roberts et al., 1996; Shephard, 2008). The combined evidence presented in these studies indicates that the health benefits of bicycling far exceed the health risks from traffic injuries, contradicting the widespread misperception that bicycling is a dangerous activity. Moreover, as bicycling levels increase, injury rates fall, making bicycling safer and providing even larger net health benefits (Elvik, 2009; Jacobsen, 2003; Robinson, 2005).
Perhaps due to the increasing evidence of the health benefits of bicycling, many government agencies and public health organizations have explicitly advocated more bicycling as a way to improve individual health as well as reduce air pollution, carbon emissions, congestion, noise, traffic dangers, and other harmful impacts of car use (BMA, 1992; Cavill et al., 2006; Godlee, 1992; OECD, 2004; USDHHS, 1996, 2008; USDOT, 1994, 2004; WHO, 2002a,b). Given the growing consensus on the benefits of bicycling, the important question for researchers is how to increase bicycling. That is the topic of this review paper. Our purpose is threefold: (1) To list, describe, and categorize the wide range of infrastructure, program, and policy interventions to promote bicycling; (2) To summarize the available information on where and to what extent these interventions are currently being implemented; and (3) To assess the actual impacts of the various interventions on levels of bicycling.

An extensive and rapidly growing literature suggests the need to facilitate bicycling through appropriate infrastructure (such as bike paths and bike parking), traffic calming, training and education programs, and other supportive measures. Countries and cities with high levels of bicycling and good safety rates tend to have extensive infrastructure, as well as pro-bicycle policies and programs, whereas those with low bicycling rates and poor safety records generally have done much less (Pucher and Dijkstra, 2003; Fietsberaad, 2006; Pucher and Buehler, 2008).

Such aggregate comparisons across cities and countries support the general importance of policies for encouraging bicycling and improving safety. However, it is not clear which measures are the most effective and should be given priority in designing and implementing a pro-bicycle policy package. This article assembles the available evidence on the actual impacts of a wide range of policies and programs, first according to specific categories of individual policy measures and then as packages of coordinated policies and programs.

Methods

We first developed a list of interventions hypothesized to encourage bicycling directly. The list did not include measures such as congestion pricing, gasoline taxation, and car parking policies, which probably influence bicycling levels indirectly. The initial list was reviewed by other experts and practitioners and expanded. Although the final list is extensive, it may exclude promising but rare or recently implemented interventions for which studies are not available.

Because few studies measuring the effects of such interventions appear in peer-reviewed journals, we conducted a broad search that also included non–peer-reviewed research found in government documents, conference proceedings, and other sources. Using the list of interventions, we conducted electronic searches using Google, Google Scholar, TRIS Online (National Transportation Library), TRANweb, MEDLINE, PUBMED, and ISI Web of Knowledge. We also consulted about 30 Internet websites devoted specifically to pedestrian and bicycling information, which post many articles and reports on policy interventions to promote bicycling. The reference lists in each of the located publications were used to identify additional information. We also contacted bicycle researchers and practitioners in the US, Europe, South America, and Australia to identify potential studies.

The small number of high quality studies prevented us from applying the strict criteria for inclusion used in other related reviews (e.g., Ogilvie et al., 2004). We decided that including a wider range of studies would help in building the evidence base and assessing research gaps and needs, particularly with respect to methodology. We only included studies that reported impacts specifically on bicycling as a dependent variable. Studies that combined both walking and bicycling as an outcome measure (e.g., minutes of physical activity) were not included, in contrast to Ogilvie et al. (2004). Combined measures were often used in studies evaluating interventions such as paths and trails, which accommodate both walking and bicycling. Many studies on bicycling interventions focus on safety measures as an outcome, including the number of crashes or interim measures such as distance between bicyclists and motor vehicles. Although real or perceived safety levels likely influence levels of bicycling, these studies were not systematically included in this review. Some examples, however, are included when studies with bicycling outcomes are not available.

Studies conducted at both the individual and aggregate (e.g., city or district) levels were included. Both revealed and stated preference studies were included. Revealed preference studies measure actual behavior, either through self-report (e.g., surveys) or more objective means (e.g., automatic counters or global positioning systems [GPS]). Stated preference studies measure people’s opinions or intended behaviors. They are often perceived as being less reliable than revealed preference studies. Stated preference methods are often used to test interventions (or packages of interventions) that do not currently exist and, therefore, could not be recorded by revealed preference methods. Sophisticated stated preference studies provide respondents pairs of choices with different characteristics. For example, a bicyclist might be asked to choose between a shorter route that does not have a bike lane and a longer route that includes a bike path.

We selected only studies that included some quantitative measure of an outcome related to bicycling. Because of the small number of studies and lack of consistency in approaches, we included a wide range of outcomes. Studies that measured the amount of bicycling were of highest priority. At the individual level, this could include, for example, the number of bicycle trips, distance bicycled, or whether or not a person was a bicyclist. At the aggregate level, the share of people bicycling to work was a common measure; the share of all trips by bicycle was reported in some studies. More indirect measures included cyclists’ opinions or ratings of interventions.

In some cases, a single evaluation was reported in more than one source, such as a government report, a conference paper, and a peer-reviewed journal article. This review includes only the journal article, unless unique information appears in one of the other sources. Finally, we limited the search to studies in English and focused on studies conducted since 1990. Our search resulted in 139 sources that included evidence of the effect of specific interventions on bicycling, of which 65 appeared in peer-reviewed publications (see Tables 1–4). That number does not include citations used for the case study cities. Nearly all of the studies were of adults, except for those that focused on school-based interventions.

Results

Travel-related infrastructure

Perhaps the most common types of intervention are those that aim to separate cyclists from motor vehicles. (See Table 1 for descriptions of each intervention and results.) Striped bike lanes and separate paths are common in North America and Europe, but many European cities also use pavement coloring and other innovations such as “cycle-tracks,” which function like a bike lane but have greater physical separation from motor vehicles (Fig. 1). Contraflow lanes permit cyclists to ride against motor vehicle traffic on one-way streets (Fig. 2). Forty studies attempted to evaluate the effect or value of bike lanes and/or separate paths. Study methodologies varied widely, including both stated and revealed preference and individual- and aggregate-level analysis. Very few of the studies were longitudinal, and they yielded few quantitative estimates of the effect of facilities on overall rates of bicycling sometimes because of the methodologies employed. For example, many of the studies used convenience samples of avid cyclists instead of random samples.

Most of the aggregate-level studies found a positive and statistically significant relationship between bike lanes and levels of bicycling, whereas the individual-level studies had mixed findings. A cross-sectional study at the city level of over 40 US cities found that each additional mile of bike lane per square mile was associated with an increase of approximately one percentage point in the share of workers regularly commuting by bicycle (Dill and Carr, 2003). A study of Seattle, Washington residents found no relationship between the presence of a bike lane (objectively measured) and the odds of bicycling, but did find that being near a path mattered. For example, people living within a half-mile of a path were at least 20% more likely to bicycle at least once a week, compared to people living between one-half and one mile away from a path (Vernez-Mounoud et al., 2005).
Austrian study found that people who agreed that there were bicycle "tracks" along their route and possible shortcuts were about twice as likely to bike as those who did not (Titze et al., 2008). One revealed preference (RP) survey of cyclists found a positive association between their overall rating of the quality of bicycle facilities and frequency of bicycle commuting (Sener et al., 2009a). One study did not find a significant relationship between ratings for the bikeability on streets around elementary schools and the number of bicycles parked at the schools (Sisson et al., 2006). Cross-sectional studies at the city or district level show positive correlation between bike lanes or paths and levels of bicycle commuting (Dill and Carr, 2003; LeClerc, 2002; Nelson and Allen, 1997; Parkin et al., 2008; Pucher and Buehler, 2005). Two longitudinal studies found that new bike lanes and paths were associated with increases in bicycle commuting, though effects were sometimes mediated (Barnes et al., 2006; Cleaveland and Douma, 2009).

Four of five RP studies conducted at the individual level did not show a positive correlation (Cervero et al., 2009; de Geus et al., 2008; Dill and Voros, 2007; Vernez-Moudon et al., 2005). Krizek and Johnson (2006) found that people living within 400 meters of a bike lane were more likely to bicycle. Two of the studies found positive association between the perception of having bike lanes and paths and bicycling (Dill and Voros, 2007; Vernez-Moudon et al., 2005). Some RP studies of route choices show that cyclists go out of their way to use bike lanes or paths (Dill, 2009; Dill and Giebe, 2008; Howard and Burns, 2001; Krizek et al., 2007).

Several stated preference (SP) studies show a preference for bike lanes over no facilities or that bike lanes would encourage more bicycling (Abraham et al., 2002; Akar and Clifton, in press; Antonakos, 1994; Bureau of Transportation Statistics, 2004; Emond et al., 2009; Hunt and Abraham, 2007; Krizek, 2006; Landis et al., 1998; Madera, 2009; Parkin et al., 2007; Stinson and Bhat, 2003; Tilahun et al., 2007; Wardman et al., 2007). Experienced cyclists may prefer bike lanes to off-road paths (Akar and Clifton, in press; Antonakos, 1994; Bureau of Transportation Statistics, 2004; Hunt and Abraham, 2007; Stinson and Bhat, 2003; Tilahun et al., 2007) or have little or no preference for striped lanes over no striping (Taylor and Mahmassani, 1996; Sener et al., 2009b).

Before-and-after counts in several North American cities and London (UK) show increases in number of cyclists after bike lanes installed (City of San Francisco, 2004; City of Toronto, 2001; City of Vancouver, 1999; Federal Highway Administration, 1994; Sallaberry, 2000; San Francisco Department of Parking and Traffic, 2001; Transport for London, 2004a). However, only one city included counts on nearby streets, where it was found that cyclists were likely diverted to the bike lane (City of San Francisco, 2004).

Four studies looked at the effect of bike lane markings on behavior related to safety, but did not include measures of changes in the amount of bicycling. (Hunter et al., 1999; Harkey and Stewart, 1998; Daff and Barton, 2005; Van Houton and Seideman, 2005).

No studies were found that assessed changes in levels of bicycling. A study of six sites in the UK concluded that the treatments were safe when designed correctly. A large majority of surveyed cyclists felt safer with the treatments (Byley and Davies, 1998). A German study found no negative effect on traffic safety (Alrutz et al., 2002). A before-after study of three locations in London found no significant change in the number of crashes. At a fourth location where bicycling flow rates were available, a significant decrease in the crash rate was found (Transport for London, 2005).

Surveys in the UK found that shared bus/bike lanes were popular with cyclists. For about one-quarter of the cyclists, the lane influenced their route choice, and few delays to buses were observed (Reid and Guthrie, 2004).
recreational facilities (AASHTO, 1999). Paths can be mixed use (including pedestrians, rollerbladers, etc.) or limited to cyclists.

20% stated they would change modes if off-road facilities were not available (Rose, 2007). Several SP studies found that less confident cyclists prefer separate paths over lanes (see On-road bicycle lanes section, above; Jackson and Ruehr, 1998). Respondents in one survey were more comfortable on a path compared to a four-lane local street with a bike lane, though there was no difference between the path and a two-lane local street with a bike lane (Emond et al., 2009).

Five sources looked at paths before and after construction or the introduction of bicycles. Two did not show a change in levels of bicycling for nearby residents (Burbridge and Goulas, in press; Evenson et al., 2005). One showed an increase in minutes of bicycling among residents living within 1.5 km, when combined with a marketing campaign (Merom et al., 2003). Two studies showed an increase in the number of cyclists (Cohen et al., 2008; Transport for London, 2004a).

One RP study found a positive correlation between cyclists' perception of facility quality and the presence of signed shared roadways, though not as strong as with bike lanes. Facility quality was then positively associated with the frequency of commuting by bicycle (Sener et al., 2009a). One SP study found that cyclists preferred residential roads designated as a bicycle route slightly more than residential roads without such designation (Abraham et al., 2002). One before-after study of new cycletracks in Copenhagen reported a 20% increase in bicycle and moped traffic and a 10% decrease in motor vehicle traffic. However, it was not known how much of the change was due to changes in route choice versus people shifting from driving or other modes to bicycling (Jensen, 2008a). An evaluation of a two-way cycletrack in London showed a decrease in the rate of bicycling crashes (Transport for London, 2005) and a 58% increase in the number of cyclists on the roadway in 3.5 years (Transport for London, 2004a). Surveys of Danish adults and German cyclists both found that respondents rated cycletracks higher than striped bike lanes (Bohle, 2000; Jensen, 2007). Two studies looked at raised and colored cycletracks through intersections in Sweden. One found that the volume of cyclists increased compared to two non-treatment intersections, and estimated that the safety risk declined (Garder et al., 1998). Several studies looked at various safety measures as outcomes, but not levels of bicycling (Konig, 2006; Jensen, 2008b; Hunter et al., 2000; Sadek et al., 2007; Hunter, 1998).

No studies were found that measured levels of bicycling. Two studies measured safety outcomes, such as distances between cyclists and parked cars and cyclists and passing motorists (Alta Planning + Design, 2004; Pein et al., 1999).

Studies show a wide range of results in terms of appropriate usage by cyclists and encroachment by motor vehicles (Allen et al., 2005; Atkins, 2005; Dalf and Barton, 2005; Hunter, 2000; Newman, 2002; Rodgers, 2005; Wall et al., 2003). Four studies did not find a reduction in conflicts, because there were either no or too few conflicts observed (Allen et al., 2005; Atkins, 2005; Hunter, 2000; Wall et al., 2003). A London study concluded that advanced stop lines did not have a significant positive or negative effect on cyclist safety (Transport for London, 2005). Surveys of cyclists in three studies indicate that a majority felt safer with the bike box (Newman, 2002; Rodgers, 2005; Wall et al., 2003). One study found that a majority of cyclists did not understand the purpose of the bike box (Hunter, 2000). One study in Davis, CA estimated that the benefits (mainly reduced crashes) greatly outweighed the costs and potential harms (including changes in vehicle capacity) of a separate bicycle phase at an intersection with a high volume of bicycle traffic connecting to an off-street path. In the 35 months before installation there were 10 auto-bicycle collisions at or near the intersection, compared to none in the 35 months afterwards (Korve and Niemeier, 2002). One study found that pavement quality was negatively correlated with the share of residents in an area bicycling to work (Parkin et al., 2008). The number of cyclists on a path in London doubled after the path was resurfaced (Transport for London, 2004a). A US study found that pavement quality was a significant predictor of cyclists' rating of a road segment (Landis et al., 1998). In one survey, cyclists rated "smooth pavement" as high as having a direct route and higher than having a bike path, though lower than having a bike lane (Antonakos, 1994).
Although a 1994 study concludes that traffic calming has its roots in neighborhood-based efforts in the Netherlands in the 1960s to tame traffic on residential streets (Clarke and Dornfeld, 1994), officially endorsed by the Dutch government in 1976, the concept spread throughout Europe and to Japan, Australia, and North America over the next decade. In 1999, the Institute of Transportation Engineers (ITE) published a report on the state of traffic calming practice in the US (Institute of Transportation Engineers, 1999). Traffic calming programs for local streets are common throughout the US, though the scale and sophistication of the programs varies considerably.

The home zone concept derives from the “woonerf” or “living yard” movement in the Netherlands in the 1960s. Home zones are common in the Netherlands, Germany, the UK, and other parts of Europe. The UK Department for Transport promotes the home zone concept. The concept has not been adopted in the US, though examples of streets that follow the principles of home zones can be found. Although common in European cities, pedestrian malls are limited in the US. Well-known examples include Pearl Street in Boulder, CO; Third Street Promenade in Santa Monica, CA; Ithaca Commons, in Ithaca, NY; and Faner Hall/Quincy Market in Boston, MA. Many cities in the US experimented with pedestrian malls in the 1960s and 1970s but later removed them when businesses in the mall failed to thrive. Car-free neighborhoods are much less common than pedestrian malls. One of the most famous examples is Vaubon in Freiberg, Germany. In North America, examples are mostly limited to resort-oriented islands, such as Mackinac Island in Michigan.

Complete streets policies, taking many different forms, establish the complete streets concept as the guiding design principle for new and rebuilt streets. Complete streets policies had been adopted by 25 local and regional governments in the US and by 10 states as of 2007 (Thunderhead Alliance, 2007). The US Congress is considering a federal complete streets policy. The number of projects built according to complete streets principles is growing.

A Netherlands study found that 0.3 fewer stops per km along a route meant a 4.9% higher share of bicycling (Rietveld and Daniel, 2004). Although a 1994 study concludes that “the experience from Europe clearly shows that bicycle use has been encouraged by traffic calming” (Clarke and Dornfeld, 1994), few rigorous studies are available to support this claim. The impact of traffic calming on vehicle speeds is well documented, but evidence on the degree to which reduced speeds lead to reductions in accidents or increases in bicycling is slimmer. Studies in Germany in the early 1980s showed a doubling of bicycling in the small town of Buxtehude (Doldissen and Draeger, 1990) and a 50% increase in bicycle use in the Berlin-Moabit area (Commission of the European Communities, 1989). A study in Japan in the 1980s found that bicycle traffic volumes rose along most routes, though the magnitude of the increase was not reported (Clarke and Dornfeld, 1994). A Danish study noted a 20% increase in bicyclists crossing a major road after traffic calming in one of three towns (Herrstedt, 1992).

In the 1990s, a traffic calming project in the city of Cambridge, Massachusetts led to an increase in perceived safety: 33% of residents reported that cyclist safety was better, while only 8% said it was worse (Watkins, 2000). In the Berlin-Moabit area, bicyclist accidents declined by 16% (Commission of the European Communities, 1989). Bicycle accidents rose in Buxtehude, but these were primarily non-injury accidents (Doldissen and Draeger, 1990). An evaluation of nine home zone schemes in the UK found no change in adult bicycle ownership. Among adults with bikes, 80% said the home zone made no difference in how often they bicycled within the zone, 10% said they bicycled more often, 10% said they bicycled less often. Among cyclists, 60% said bicycling in home zones was not different, 30% said more pleasant, 10% said less pleasant. Among children with bicycles, 57% used it with the same frequency, 22% used it more often, 21% used it less often; 28% thought bicycling more fun now, 10% less fun, and 62% about the same (Webster et al., 2006).

Several case studies provide evidence of a shift in mode split for people entering the central business district after conversion to a pedestrian mall, though the impact on bicycling appears limited. In Bologna, Italy, vehicle traffic declined by 50%, and 8% of people arriving at the center came by bicycle after the conversion (Topp and Pharoah, 1994). In Lubeck, Germany, of those who used to drive, 12% switched to transit, walking, or bicycling; bicycling was not separately reported (Topp and Pharoah, 1994). In Aachen, Germany, car travel declined from 44% to 36%, but bicycling stayed constant at 3% (Topp and Pharoah, 1994).

No studies on the impact of complete streets policies or projects on bicycling levels are publicly available at this time.

</table>

Stated preference studies almost uniformly found that both cyclists and non-cyclists preferred having bike lanes to riding in mixed traffic. The findings from the studies of off-street paths were varied, with some showing positive associations and others showing no statistically significant relationship. Only four studies examined bicycle boulevards and traffic-protected cycletracks, types of roadway infrastructure less common in the US. The findings generally showed a positive association between these facilities and bicycling, though without good estimates of the quantitative effects on actual bicycling rates.

Bicycle boulevards employ techniques similar to those for traffic calming streets to reduce the number and speed of cars (Fig. 3). Of the six studies on traffic calming, all but one found positive results, though none rigorously measured the effects on the amount of bicycling. Although cat-free zones, home zones, and “complete streets” also improve the street environment for bicyclists, no studies have measured their effects on the amount of bicycling (see Table 1 for definitions and more detail).

Several studies point to the need to consider characteristics of the bicyclist. At least three studies found differences in facility preferences between men and women, with women generally more attracted to bike parking and end-of-trip facilities. Table 2

</table>
found an increased perception of safety. Other traffic controls may also affect bicycling. For example, one study shows that a decrease in the number of stops along a route (e.g., due to stop signs or signals) increases bicycling (Rietveld and Daniel, 2004).

### End-of-trip facilities and transit integration

There is consensus on the need to provide good bike parking for cyclists—especially secure, sheltered parking to prevent theft and to protect bicycles from inclement weather (AASHTO, 1999; APBP, 2002; Fietsberaad, 2006; Litman, 2009; Netherlands Ministry of Transport, 2009; Pucher, 2008; USDOT, 2007). Perhaps due to the obvious importance of bike parking, few studies have even attempted to measure the impact of bike parking on bicycling levels. Moreover, it is not clear to what extent provision of parking facilities follows increased bicycling levels instead of preceding and encouraging more bicycling. The causation is almost certainly in both directions (Fietsberaad, 2006; USDOT, 2007; Netherlands Ministry of Transport, 2009).

Most of the information in Table 2 relates to the nature and extent of the various types of end-of-trip facilities. In virtually every city we reviewed, the supply of bike parking has been expanding, and many cities have been providing increasing amounts of sheltered parking, guarded parking, and state-of-the-art bike stations which provide a full range of services, including storage, rental, repair, and showers (Fig. 6). No comprehensive statistics on bike parking supply for any country were found, and most city statistics only include publicly provided parking spaces.

Some cities monitor the usage of parking facilities, but that is only an indirect reflection of bicycling rates, because bicycles can be parked for hours, days, or even weeks. There are few rigorous studies of the impacts of bike parking on bicycling levels. Using multivariate analysis of the UK’s National Travel Survey—combined with stated preference survey data—Wardman et al. (2007) estimated statistically significant impacts of parking and showers on bicycling levels. Compared to a baseline level of 5.8% of work trips by bicycle, providing outdoor bike parking was estimated to raise the bicycle share to 6.3%. Secure indoor parking raised the bicycle share to 6.6%, and to 7.1% when combined with shower facilities. In a stated preference experiment, Hunt and Abraham (2007) surveyed cyclists in Edmonton, Canada and found a statistically significant impact of secure parking at the destination, equivalent to a reduction of 27 minutes of in-route bicycling time. They estimated a much smaller, but statistically significant impact of shower facilities, equivalent to a reduction of 4 minutes of in-route bicycling time.

Bike parking is one of the key aspects of integrating bicycling with public transport. As noted in Table 3, the focus in Europe and Japan has been on providing massive amounts of bike parking at rail stations. Bike parking at bus stops is far less common and is mostly found in northern Europe, where few if any buses are equipped with bike racks.

Martens (2007) surveyed the impacts of improved bike parking at both rail stations and bus stops in the Netherlands, in the context of specific pilot projects during the 1990s to improve integration of bicycling with public transport. He found significant increases in both public transport use and bicycling, but mainly for bicycle trips between home and the suburban rail station (access trip) and far less for bicycle trips between the terminal station and the activity end of the trip (egress trip). Taylor and Mahmassani (1996) estimated a strong preference of cyclists for secure parking at public transport stations, especially in the form of bike lockers.

Martens (2007) notes the success of the Dutch public transport bicycle system (OV-Fiets), which provides convenient and inexpensive short-term bicycle rentals (using automated card technology) for trips from major train stations to the final destinations of travelers, usually near the city center. The evidence compiled by Martens confirms that better integration of bicycling with public transport leads to more bike and ride trips, and probably to more bicycling overall.

Bicycles on buses and bicycles on rail vehicles are also important forms of integration with public transport, but no studies have explicitly measured their impact on bicycling levels (USDOT, 1998; TRB, 2005). Some public transport systems in North America (which has most of the world’s rack-equipped buses) report usage rates for bike racks on their buses, but time trends are not usually provided, and the results, at any rate, would not necessarily translate into more bicycling.

### Table 3

<table>
<thead>
<tr>
<th>Measure</th>
<th>Examples and extent of implementation</th>
<th>Measured effects on bicycling</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parking at rail stations</strong></td>
<td>Most important form of integration with public transport (PT) in Europe and Japan, with large amounts of bike parking at most suburban rail and many metro stations, often in form of bike stations (Pucher and Buehler, 2008; Fietsberaad, 2006; Dutch National Railways, 2009); massive bike parking at Japanese rail stations, with 740,000 bikes parked at Tokyo’s metro and train stations every day (Harden, 2008); over 350,000 bike racks at Dutch train stations (Martens, 2007; Dutch National Railways, 2009).</td>
<td>Rietveld (2000); Martens (2004 and 2007); Brunsing (1997); Hegger (2007); McClintock and Morris (2003); Pucher and Buehler (in press); and Netherlands Ministry of Transport (2009) found that provision of good bike parking at PT stations increases PT use as well as levels of bicycling. TRB (2005) estimates that all forms of bike and ride are much cheaper than park and ride for access to PT stops.</td>
</tr>
<tr>
<td><strong>Parking at bus stops</strong></td>
<td>Less common and mostly restricted to northern Europe, due to lack of bike racks on buses.</td>
<td>No studies available.</td>
</tr>
<tr>
<td><strong>Bike racks on buses</strong></td>
<td>Most common in North America, with 72% of US buses equipped with bike racks, and 80% of Canadian buses; rare in Europe (APTA, 2008; TRB, 2005; Pucher and Buehler, in press; Thunderhead Alliance, 2007).</td>
<td>Most studies focus on impacts of bike racks on bus use, and find positive impacts, generating more revenues than cost of installing racks (Hagelin, 2005). Surveys of PT systems find high and increasing use of bike racks (USDOT, 1998; TRB, 2005). Evidence suggests high level of use but insufficient capacity to handle bikes during peak hours; no formal studies of impacts on bicycling levels, but probably positive, because it helps cyclists cover long portions of trip by PT while using their bikes to reach PT stops and access destinations (USDOT, 1998; TRB, 2005; Pucher and Buehler, in press).</td>
</tr>
<tr>
<td><strong>Bikes on rail cars</strong></td>
<td>Usually permitted during off-peak hours on most suburban rail, metro, and light rail systems in both Europe and North America; often special space on rail cars reserved for bikes, sometimes with bike racks or hooks; many systems prohibit bikes during peak hours (Pucher and Buehler, in press; TRB, 2005).</td>
<td>Martens (2007) and Litman (2009) report increased bicycling as well as increased PT usage as a result of such rental programs.</td>
</tr>
<tr>
<td><strong>Short-term rental bikes</strong></td>
<td>Most widely implemented in Europe, using Smart Card technology, with OV-Fiets public transport bicycle rentals at 156 Dutch rail stations and Call-a-Bike rentals at 16 German train stations (Martens, 2007; Pucher and Buehler, 2008), but expanding with new bicycle rental systems such as Velib’ in Paris, Velo’v in Lyon, and Bicing in Barcelona, with many rental stations near metro and train stations (Litman, 2009; Martens, 2007; Holtzman, 2006; DeMaio and Gifford, 2004).</td>
<td>Martens (2007) notes the success of the Dutch public transport bicycle system (OV-Fiets), which provides convenient and inexpensive short-term bicycle rentals (using automated card technology) for trips from major train stations to the final destinations of travelers, usually near the city center. The evidence compiled by Martens confirms that better integration of bicycling with public transport leads to more bike and ride trips, and probably to more bicycling overall.</td>
</tr>
</tbody>
</table>
A review of before-and-after evaluations found an increase in bicycle trips in 10 of 11 Australian neighborhood programs, as well as increases in bicycling in 8 of 10 worksite programs (Australian Greenhouse Office, 2005; Cooper, 2007; Portland Office of Transportation, 2007; Socialdata, 2006). The number and variety of programs in this category appear to be growing, although no inventory is available. The first time riders reportedly affected over 111 million inhabitants in 1,035 participating cities and 428 supporting cities during the events (Cairns et al., 2004). Programs are more common in Europe than in the US.

### Table 4
Programs and legal interventions to promote bicycling.

<table>
<thead>
<tr>
<th>Measure</th>
<th>Description</th>
<th>Examples and extent of implementation</th>
<th>Measured effects on amount of bicycling</th>

<tbody>
<tr>
<td><strong>General Travel Programs</strong></td>
<td>Employer-based programs that aim to reduce vehicle travel, usually by shifting commute mode to transit, walking, and/or bicycling. Programs, often mandated by law, may include promotions, financial incentives, and provision of facilities. Called ”Travel Plans” in the UK.</td>
<td>Programs are common in the US in metropolitan areas with high levels of congestion and/or air quality problems.</td>
<td>Evaluations usually focus on reductions in vehicle travel rather than increases in bicycling. Examples in the UK show increases in bicycling: Manchester Airport tripled bicycle trips to work, with parking charges and improved bicycle access and facilities, between 1996 and 2000; in Stockley Park, bicycling more than doubled in late 1990s (Rye, 2002). A parking cash-out program in the US led to a 39% increase in walking and bicycling combined (Shoup, 1997). In a study of the “Mobility Management” policy in the Netherlands, eight employees reported increases in bicycling (1% to 8%), one no change, and one a decrease (3%) (Touwen, 1997). A ”Walk in to Work Out” educational campaign that included substantial information on bicycling had no impact on bicycling at three Glasgow workplaces (Mutrie et al., 2002). One stated preference study concluded that financial incentives of £2 per day would not increase bicycling commuting (Ryley, 2006).</td>
</tr>
<tr>
<td><strong>Trip Reduction Programs</strong></td>
<td>Comprehensive marketing programs aimed at individuals in a neighborhood, school, or worksite. Programs usually involve targeted information, events, and incentives, such as transit passes or coupons to bicycle stores. Programs were first implemented in Europe by Socialdata and targeted public transport (Brog, 1998). TravelSmart programs have been implemented throughout Australia and in a handful of US cities, though the number is increasing. More recent programs in US cities are branded under different names, such as SmartTrips in Portland, OR.</td>
<td>The number and variety of programs in this category appear to be growing, although no inventory is available. The ”In Town Without My Car!” program, which dates back to the mid-1990s, reportedly affected over 111 million inhabitants in 1,035 participating cities and 428 supporting cities in 2003 (Cairns et al., 2004). Programs are more common in Europe than in the US.</td>
<td>A review of before-and-after evaluations found an increase in bicycle trips in 10 of 11 Australian neighborhood programs, as well as increases in bicycling in 8 of 10 worksite programs (Australian Greenhouse Office, 2005). Evaluations of programs in Portland and other US cities found increases in the share of all daily trips made on bicycle (Brog and Barta, 2007; Cooper, 2007; Portland Office of Transportation, 2007; Socialdata America, 2005; City of Portland Office of Transportation, 2006; City of Portland Office of Transportation, 2005). In eight neighborhood programs in Australia and the US, the increase ranged from one to two percentage points (e.g., from 3% to 4% of all trips); in the other cases, the increase was less than one-half of one percentage point. Many of the programs show larger increases in walking and transit use, also targets of the marketing. Evaluations of media campaigns tend to focus on marketing-style outcomes—for example, how many people noticed a campaign, what they remember from it rather than change in travel behavior. Awareness of travel behavior campaigns range from 17% to 76%; 20% to 40% is common (Cairns et al., 2004). The You-Move-NRW campaign in North Rhine-Westphalia, Germany in 2002, involving a contest for school children to propose projects to reduce driving, led to an increase in transit use but a decline in bicycling among participants (Reutter, 2004). Only a handful of studies so far measure the effects of SRTS programs on bicycling. A study in Marin County, CA, one of the earliest programs in the US, found a 114% increase in the number of students bicycling to school (Staunton et al., 2003). An examination of 12 California school districts found that schools with a biking program had 21% higher levels of bicycling among students, compared to schools without a biking program (Boarnet et al., 2005). There are indications that bicycle programs are more common in Europe than in the US. The You-Move-NRW campaign in North Rhine-Westphalia, Germany in 2002, involving a contest for school children to propose projects to reduce driving, led to an increase in transit use but a decline in bicycling among participants (Reutter, 2004).</td>
</tr>
<tr>
<td><strong>Individualized Marketing (also known as TravelSmart and SmartTrips)</strong></td>
<td>A wide variety of programs designed to reduce driving and increase use of transit, walking, and bicycling, usually implemented by local governments or community organizations.</td>
<td>The movement is believed to have started in Denmark in the 1970s. Programs in the US increased in number starting in the 1990s (Boarnet et al., 2005). SRTS is now funded at the federal level, with programs in every state (Davidson et al., 2008). Nearly 4,500 schools were reported to be participating in state-funded programs at the end of 2008 (National Center for Safe Routes to School, 2008).</td>
<td></td>
</tr>
<tr>
<td><strong>Travel Awareness Programs</strong></td>
<td>Safe Routes to School (SR2S or SRTS) programs include education, encouragement, infrastructure, and enforcement programs aimed at increasing the safety and number of students walking and bicycling to school.</td>
<td>The most comprehensive study of these events reports minutes of physical activity generated by the ciclovias without distinguishing between bicycling and other means of movement (Sarmiento et al., in press). Using cross-sectional data, Cervero et al. (2009) found that proximity to ciclovia bikeways is associated with higher levels of ciclovia use. Also using cross-sectional data, Gomez et al. (2005) found an association between recreational riding on ciclovias and utilitarian cycling such as bike trips to work. There is some evidence that BWDs increase bicycling beyond the event. The number of &quot;first time riders&quot; has increased in many programs: in Seattle, from 845 new commuters in 2004 to 2474 in 2008; in Portland, from 413 in 2002 to 2869 in 2008 (LAB, 2008). In San Francisco in 2008, bicycle counts at a central point were 100% higher on BWD and 25.4% higher several weeks later; bicycle share was 48.3% before BWD, 64.1% on BWD, and 51.8% afterwards (LAB, 2008). In Victoria, Australia, 27% of first time riders on BWD were still bicycling to work 5 months later (Rose and Marfurt, 2007). The most comprehensive study of these events reports minutes of physical activity generated by the ciclovias without distinguishing between bicycling and other means of movement (Sarmiento et al., in press). Using cross-sectional data, Cervero et al. (2009) found that proximity to ciclovia bikeways is associated with higher levels of ciclovia use. Also using cross-sectional data, Gomez et al. (2005) found an association between recreational riding on ciclovias and utilitarian cycling such as bike trips to work.</td>
<td></td>
</tr>
<tr>
<td><strong>Bicycling-Specific Programs</strong></td>
<td>Bike-to-Work Days (BWDs) are promotional events that encourage commuters to try bicycling. Events may take place over a day, week, or month, and may include free breakfasts, giveaways, contests, and other activities. Bike-to-Work events are popular in metropolitan areas in the US. The number of programs and the numbers of participants in individual programs have increased.</td>
<td>These events started in the 1960s in San Francisco, Seattle, and Sao Paolo, and gradually spread throughout the Americas (Sarmiento et al., in press). Since 2000, growth has been rapid: 25 new programs have started, for a total of 38 cities with ongoing programs in the Americas. South America</td>
<td></td>
</tr>
<tr>
<td><strong>Ciclovias (or &quot;ciclovias-recreativas&quot;)</strong></td>
<td>Free mass recreational programs where streets are temporarily closed to motorized traffic and reserved for use by pedestrians, runners, rollerbladers, and cyclists.</td>
<td>Nearly 4,500 schools were reported to be participating in state-funded programs at the end of 2008 (National Center for Safe Routes to School, 2008).</td>
<td></td>
</tr>
</tbody>
</table>

(continued on next page)
### General Travel Programs

#### Ciclovias (or “ciclovias-recreativa”)
- Currently has the largest and most frequent ciclovias. Many other cities in the Americas, Europe, and Australia occasionally close off streets for non-motorized events, often as part of car-free days.
- Work. Bogota has the world’s largest ciclovia, with 123 km of streets closed to cars and 700,000 to 1 million participants. Bogota’s bicycle mode share has tripled as the popularity of the ciclovia has grown, but the scale of this ciclovia makes it an exceptional case (Parra et al., 2007; IDRD, 2004; IDU, 2009; Montezuma, 2005; Despascio, 2008).

### Other Bicycle Promotions

- Examples of other types of bicycle promotions include bicycle film festivals (Horton and Salkeld, 2006), bicycle “buses” (Bauman et al., 2008), recreational bicycle events (Bauman et al., 2008), and bicycle awareness campaigns (Greig, 2001).

### Education/Training

- A variety of programs designed to increase bicycling skills and knowledge of bicycling laws.
- In the US, the League of American Bicyclists certifies trainers for six different courses; 200 instructors were certified in 2005. Other education/training programs are offered by local governments and community organizations. No inventory of all such programs is available.

### Bicycle Access Programs

#### Bicycle Sharing Programs
- These programs offer short-term rentals for a nominal fee and sometimes require a one-time or annual membership fee. Bicycles can be picked up and returned at designated spots around the city, usually through an automated system.
- Bicycle sharing programs have evolved through three generations since the 1960s, starting with a free bicycle program established in Amsterdam in 1964. Recent programs employ advanced technology to provide access to bikes and to track them. Bicycle sharing programs are already operating in 89 European cities and are now spreading to cities elsewhere in the world, including the US (DeMaio, 2009a and 2009b).

### Other Access Programs

- Programs to increase bicycle access include giveaway programs, loaner programs, fleet programs, and service and repair programs.
- No inventory of such programs is available.

### Legal Interventions

#### Helmet Laws
- Helmet laws require cyclists of all ages or of specified ages (e.g., under 18 years old) to wear helmets.
- In the US, helmet laws were first adopted by state and local governments in 1985. There are 22 state and at least 192 local helmet laws (Bicycle Helmet Safety Institute (BHSl), 2009). In Australia, helmets are mandatory in all states and territories. Helmets are generally not required in European countries.

#### Speed Limits
- Reduced speed limits for vehicle traffic to improve safety for cyclists and pedestrians and to improve environmental quality (e.g., reduce noise).
- Reduced speed limits are often put in place as a part of traffic calming programs (see Table 1). The Department for Transport in the UK has promoted 20 mph zones.

<tr>
<td><strong>Other Bicycle Promotions</strong></td>
<td>Examples of other types of bicycle promotions include bicycle film festivals (Horton and Salkeld, 2006), bicycle “buses” (Bauman et al., 2008), recreational bicycle events (Bauman et al., 2008), and bicycle awareness campaigns (Greig, 2001).</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Education/Training</strong></td>
<td>A variety of programs designed to increase bicycling skills and knowledge of bicycling laws. In the US, the League of American Bicyclists certifies trainers for six different courses; 200 instructors were certified in 2005. Other education/training programs are offered by local governments and community organizations. No inventory of all such programs is available.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Bicycle Access Programs</strong></td>
<td>Bicycle Sharing Programs</td>
<td>These programs offer short-term rentals for a nominal fee and sometimes require a one-time or annual membership fee. Bicycles can be picked up and returned at designated spots around the city, usually through an automated system. Bicycle sharing programs have evolved through three generations since the 1960s, starting with a free bicycle program established in Amsterdam in 1964. Recent programs employ advanced technology to provide access to bikes and to track them. Bicycle sharing programs are already operating in 89 European cities and are now spreading to cities elsewhere in the world, including the US (DeMaio, 2009a and 2009b).</td>
<td>Evaluations focus on use of the program rather than impact on bicycling overall. Rentals per bicycle per day average 5–12 in Paris, 6.4 in Lyon, and 6 in Barcelona (Ecoplan, 2009; DeMaio, 2009a; Holtzman, 2008; Buehrmann, 2008). Estimated trips generated per day by bicycle sharing range from 19,100 in Lyon, to 30,000 in Barcelona and 70,000–145,000 in Paris. (Ecoplan, 2009; DeMaio, 2009a; Bonnette, 2007). Evidence on increases in bicycle mode share after implementation of bicycle sharing programs is confounded by improvements in bicycling facilities made at the same time. Bicycle share reportedly increased from 0.75% in 2005 to 1.76% in 2007 in Barcelona (Romero, 2008), from 1.0% in 2001 to 2.5% in 2007 in Paris (Nadal, 2007; City of Paris, 2007), and from 0.5% in 1995 to 2% in 2006 in Lyon, with a 75% increase in bicycle counts from 2005 to 2007 (Bonnette, 2007; Velo’s, 2009). In London, 68% of OYBike trips were for leisure or recreation; 6% of users reported shifting from driving and 34% from transit, while 23% said they would not have travelled (Noland and Ishaque, 2006).</td>
</tr>
<tr>
<td><strong>Other Access Programs</strong></td>
<td>Programs to increase bicycle access include giveaway programs, loaner programs, fleet programs, and service and repair programs.</td>
<td>No inventory of such programs is available.</td>
<td></td>
</tr>
<tr>
<td><strong>Legal Interventions</strong></td>
<td>Helmet Laws</td>
<td>Helmet laws require cyclists of all ages or of specified ages (e.g., under 18 years old) to wear helmets. In the US, helmet laws were first adopted by state and local governments in 1985. There are 22 state and at least 192 local helmet laws (Bicycle Helmet Safety Institute (BHSl), 2009). In Australia, helmets are mandatory in all states and territories. Helmets are generally not required in European countries.</td>
<td>Mandatory helmet laws have been shown to increase helmet use but also to reduce bicycling. Studies in Australia in the 1990s found declines in bicycle counts one year after the implementation of a helmet law of 36% in Melbourne, 36% in New South Wales, and 20% in Perth (Clarke, 2006; Robinson, 2006).</td>
</tr>
<tr>
<td><strong>Speed Limits</strong></td>
<td>Reduced speed limits for vehicle traffic to improve safety for cyclists and pedestrians and to improve environmental quality (e.g., reduce noise). Reduced speed limits are often put in place as a part of traffic calming programs (see Table 1). The Department for Transport in the UK has promoted 20 mph zones.</td>
<td>Reduced speed limits for vehicles potentially increase bicycling in two ways: by increasing the speed of bicycling relative to the speed of driving, and by increasing the safety of bicycling. In Graz, Austria a general 30 km/hr speed limit reduced bicyclist accidents by 4% (Sammer, 1997). Widespread automobile speed limits in Hilden, Germany led to a significant increase in bicycling (Bauman et al., 2008). Studies in the UK show an increase in willingness of residents to bicycle but no evidence of an actual increase in bicycling in 20 mph zones (Rabie Group, 2001).</td>
<td></td>
</tr>
</tbody>
</table>
In short, the few available studies confirm the logical assumption that better bike parking and better integration of bicycling with public transport encourage more bicycling. But the empirical evidence is limited to a few cities, making the results difficult to generalize.

Programs

Programmatic interventions aim to increase bicycling through promotional activities, media campaigns, educational events, and other means (Table 4). Many programs target travel in general, with the goal of reducing vehicle travel by shifting trips to transit, walking, or bicycling. Examples include trip reduction programs, individualized marketing programs, and travel awareness programs, generally focusing on adults. Safe Routes to School programs focus on children, although infrastructure improvements near schools could also influence adult behavior (Watson and Dannenberg, 2008). Programs that target bicycling specifically include Bike-to-Work Days (or weeks or months) and other promotions, as well as training events.

Evidence on the effect of general travel programs on bicycling is slim. Most evaluations focus on vehicle trip reduction, and impacts on bicycling are often not reported or even measured. The few studies
available suggest limited impacts on bicycling, even when programs have a significant effect on vehicle travel; increases in transit use and walking exceed increases in bicycling, in all studies reviewed. Safe Routes to School programs have emphasized walking more than bicycling, and only one study showed a significant increase in the number of students bicycling to school (Staunton et al., 2003).

The findings for bicycle-specific programs are more encouraging, though few rigorous evaluations of these programs are available. Participation in Bike-to-Work Days is increasing in many cities, particularly by new bicycle commuters. In San Francisco, bicycle counts remained 25.4% higher one month after the event (LAB, 2008); in Victoria, Australia, over one quarter of first-time cyclists were still bicycling five months later (Rose and Marfurt, 2007). Other events and promotions have also led to an increase in bicycling. One study shows a lasting effect of a bicycling skills program (Bauman et al., 2008). "Ciclovias" are events where streets are temporarily closed to motor traffic, usually on weekends. They have become more common throughout the Americas and attract large numbers of bicyclists (Sarmiento et al., in press). One study in Bogota found that riding in ciclovias was associated with more utilitarian cycling as well (Gomez et al., 2005).

Bicycle access

People cannot bicycle if they do not have access to a bicycle, and studies show that the availability of a bicycle in a household is the strongest single predictor of bicycling for transportation (Cervero et al., 2009). Several different kinds of programs aim to increase access to bicycles, either through facilitating ownership or enabling temporary use of a bicycle (Table 4). Bike sharing programs, sometimes called city bike programs, have grown in popularity throughout the world.

The impacts of these programs are hard to assess, as they are often accompanied by expansion of the bicycle network in anticipation of increased bicycling. Available studies show that these programs are well used and that bicycling has increased in cities that have implemented bike sharing programs. The proportion of trips by bicycle increased from 0.75% to 1.76% in Barcelona (Romero, 2008) and from 1.0% to 2.5% in Paris (Nadal, 2007; City of Paris, 2007). In Lyon, bicycle counts increased 75% after implementation of the Velo'v program, with bicycle proportion of trips reaching 2% in 2007 (Bonnette, 2007; Velo'v, 2009). A study of the OYBike in London showed that 40% of users shifted from motorized modes (Noland and Ishaque, 2006). These results are confounded, however, by improvements in bicycling facilities implemented at the same time as the bike sharing program. Programs in which participants are given bicycles have also led to an increase in bicycling.

Legal issues

Traffic laws may affect bicycling in different ways (Table 4). Bicycle helmet laws have been controversial. Helmets can help prevent head injuries in falls and crashes, but laws requiring helmet use have been shown to reduce bicycling (Clarke, 2006; Robinson, 2006). Reduced speed limits for motor vehicles increase bicycling in two ways: by increasing the speed of bicycling relative to the speed of driving, and by increasing the safety of bicycling. Most studies, though not all, show an increase in bicycling with lower automobile speed limits.

Case studies of comprehensive packages

It is difficult to isolate the separate impacts of individual policy interventions designed to promote bicycling. For example, the impacts of improved bike parking, bicycling training, and individualized
marketing are probably influenced by the extent and quality of the bikeway network. Similarly, bike-to-school and bike-to-work programs are more likely to be successful in traffic-calmed residential neighborhoods. In short, measures to promote bicycling are expected to be interactive and synergistic.

Case studies provide an opportunity to examine the impacts of packages of mutually supportive pro-bicycle policies. Table 5 summarizes case studies of 14 cities that implemented a wide range of measures to increase bicycling and improve safety. Most of the information comes from detailed case studies of bicycling trends and policies published in Fietsberaad (2006), Pucher and Buehler (2007), Buehler and Handy (2008), and Buehler and Pucher (2009). Some of the information, however, is based on data collected from primary sources for this review (see Table 5 for details).

The most important message from Table 5 is that some cities, even very large cities, have dramatically raised bicycling levels while also improving bicycling safety. Berlin, for example, almost quadrupled the number of bicycle trips between 1970 and 2001 and doubled the bicycle share of trips from 5% in 1990 to 10% in 2007. In spite of the sharp rise in bicycling, serious injuries in Berlin fell by 38% from 1992 to 2006. In only six years, the bicycle share of trips within the City of Paris more than doubled from 1% in 2001 to 2.5% in 2007. The bicycle share of trips in Bogota quadrupled from 0.8% in 1995 to 3.2% in 2006. The total number of bicycle trips in London...

| Amsterdam, NL (735,000) | 1970-2008 | 25% to 37% | • Introduction of Bicing bicycle sharing program in 2005, since expanded to 6,000 short-term rental bikes in 2008, with over 400 bike rental stations  
• Extensive marketing in schools, combined with annual bike week with lots of special events, bicycle rides, informational workshops, etc.  
• Increased bike parking throughout city: 13,000 additional racks in 2007 and 2008, total of 20,392 in 2008  
• Introduction of four traffic calmed zones with 30 km/hr speed limits  
• Free bicycle registration and engraving of numbers on bikes to prevent theft  
• Introduction of Bicing bicycle sharing program in 2005, since expanded to 6,000 short-term rental bikes in 2008, with over 400 bike rental stations  
• Extensive marketing in schools, combined with annual bike week with lots of special events, bicycle rides, informational workshops, etc.  
• Increased bike parking throughout city: 13,000 additional racks in 2007 and 2008, total of 20,392 in 2008  
• Introduction of four traffic calmed zones with 30 km/hr speed limits  
• Free bicycle registration and engraving of numbers on bikes to prevent theft  
• Doubling of separate bicycling facilities between 1980 and 2007, with 450 km in 2006, including construction of many bicycle bridges and short-cuts to create a complete network of separate bicycling facilities  
• Intersection improvements, advance stop lines and bike boxes, bicycle access lanes, priority traffic signals for cyclists  
• Bi-directional travel permitted for cyclists on many one-way streets  
• Extensive bike parking at all train stations; big expansion of guarded, sheltered bike parking  
• On-bikes (public transport bikes) for convenient, cheap, short-term rental at key train stations  
• Car-free zones in city center; many residential streets are traffic calmed at 30 km/hr, including some woonerfs ("living yards") with 7 km/hr limit  
• Sharp reduction in car parking in city center  
• Mandatory bicycling education for all schoolchildren |
| Portland, OR (576,000) | 1970-2008 | 25% to 38% | • Bicycle share increased from 25% of trips in 1970 to 38% in 2005 for 40+ age group; 70% increase in total bicycle trips 1970–2006 (36% of work trips in 2006); 60% decline in serious injuries 1995–2006.  
• A 247% increase in the number of miles of bikeways (lanes, paths, and boulevards) from 79 in 1991 to 274 in 2008  
• Colored bike lanes installed at several places of potential bicycle–motor vehicle conflict, assigning right of way to the cyclist  
• Special bicycle-only signals at four difficult intersections. Loop detectors for bicycles at all actuated traffic signals on bicycle routes. Bike boxes at 10 intersections  
• Bicycle parking required in new development. City installs parking at other locations, including removing on-street parking for bicycle parking “corrals.”  
• Bike racks on all transit buses, and bikes allowed on trains  
• First “Bike Sundays” held in 2008, closing city streets in one neighborhood to motor vehicles, similar to ciclovias  
• Education and marketing events conducted year-round and during SmartTrips program each summer. City-wide and neighborhood bicycle maps provided for free.  
• Car-free zones in city center; many residential streets are traffic calmed at 30 km/hr or 20 km/hr  
• Mandatory bicycling education for all schoolchildren  
• Over 20,000 bike parking spaces (but not enough)  
• Innovative bi-annual survey of cyclists to evaluate bicycling conditions  
• Pioneered city bikes program, which places 2,000 free bikes at 110 locations throughout the city; only small deposit required |
| Copenhagen, DK (500,000) | 1998-2005 | 25% to 38% | • Since 1970s, massive expansion of fully separate bike paths and cycletracks protected by curb from motor vehicle traffic (345 km in 2004) plus 14 km of unprotected bicycle lanes  
• Special intersection modifications: advance stop lines and bike boxes, bicycle access lanes, priority traffic signals for cyclists, bright blue marking of bike lanes crossing intersections  
• Green wave for cyclists, with traffic signals timed to cyclist speeds  
• Bi-directional travel permitted for cyclists on one-way streets  
• Guarded parking facilities increased from one in 1982 to 30 in 2006; 15 schools had guarded bike parking  
• Car-free zones and reduced car parking in city center; many residential areas are traffic calmed at 30 km/hr or 20 km/hr  
• Mandatory bicycling education for all schoolchildren  
• Comprehensive system of directional signs  
• Mandatory bicycling education for all schoolchildren  
• Wide range of special bicycle rides, promotional events  
• Bike station at the main train station and bus terminal, with parking for 3,500 bikes plus bike rentals, repairs, accessories, washing, and touring information. Also, large amounts of bike parking at all suburban rail stations throughout the city and region; bike station with 300 spaces in shopping district.  
• Over 20,000 bike parking spaces (but not enough)  
• Innovative bi-annual survey of cyclists to evaluate bicycling conditions  
• Pioneered city bikes program, which places 2,000 free bikes at 110 locations throughout the city; only small deposit required  
• More than doubled network of separate bike paths and lanes from 145 km in 1975 to 320 km in 2005, including 5 km bicycle expressway and 12 bicycling streets  
• Large car-free zones in city center; almost all residential streets traffic calmed at 30 km/hr, including home zones calmed to 7 km/hr; many contraflow streets for cyclists  
• Intersections with advance stop lines and bike boxes for cyclists, advance green lights, bicycle turning lanes, and special bicycle access lanes, as well as special colored marking of lanes crossing intersection  
• Bike station at the main train station and bus terminal, with parking for 3,500 bikes plus bike rentals, repairs, accessories, washing, and touring information. Also, large amounts of bike parking at all suburban rail stations throughout the city and region; bike station with 300 spaces in shopping district.  
• Comprehensive system of directional signs  
• Mandatory bicycling education for all schoolchildren  
• Wide range of special bicycle rides, promotional events |
| Muenster, GER (278,000) | 1982-2001 | 25% to 35% | • Share of workers commuting by bicycle rose from 1.1% in 1990 to 1.8% in 2000 and 6.0% in 2008. Number of workers commuting by bicycle increased 60% from 1990 to 2008, while the number of workers increased only 36%. The number of bicycles crossing four bridges into downtown increased 36% from 1992 to 2008. Number of reported crashes increased only 14% over same period.  
• A 247% increase in the number of miles of bikeways (lanes, paths, and boulevards) from 79 in 1991 to 274 in 2008  
• Colored bike lanes installed at several places of potential bicycle–motor vehicle conflict, assigning right of way to the cyclist  
• Special bicycle-only signals at four difficult intersections. Loop detectors for bicycles at all actuated traffic signals on bicycle routes. Bike boxes at 10 intersections

</table>
doubled between 2000 and 2008, while bicyclist injuries fell by 12% over the same period. Amsterdam raised the bicycle share of trips from 25% in 1970 to 37% in 2005; serious bicyclist injuries fell by 40% between 1985 and 2005. From 1995 to 2003, the bicycle share of trips in Copenhagen rose from 25% to 38% among those aged 40 years and older. Yet, there was a 60% decline in serious injuries. Between 1990 and 2008, the number of workers commuting mainly by bicycle in Portland, Oregon increased over 600%, while the share of workers commuting by bicycle rose from 1.1% to 6.0%.

Of the medium-sized cities in Table 5, Freiburg, Germany reported the largest increase in bicycling, almost doubling the bicycle share of trips from 15% in 1982 to 27% in 2007. Modest growth was reported for Muenster, Germany (from 29% to 35% of trips); Odense, Denmark (23% to 25%); and Groningen, Netherlands (stable at around 40%). These data suggest that it may be difficult to increase bicycling beyond already high levels. In both Odense and Groningen, however, the number of serious bicycling injuries fell sharply.

The two smallest cities shown are both in the US and provide interesting contrasts. In Boulder, Colorado, the share of workers commuting by bicycle rose from 3.8% in 1980 to 6.9% in 2000 and 8.8% in 2006 in response to an aggressive program of bikeway expansion and complementary pro-bicycle measures. By comparison, the share of workers commuting by bicycle in Davis, California fell from 28% in 1980 to 14% in 2000, in spite of extensive bikeways and bike parking. The decline of bicycling to work in Davis is mainly attributable to a sharp increase in long-distance commuting to jobs in other cities in the Sacramento and San Francisco areas.

The 14 cities showcased in Table 5 are not necessarily representative, but they illustrate a wide range of policy interventions. With so many measures integrated into the pro-bicycle policy package of each city, it would be virtually impossible to disentangle the impacts of each individual measure. Only in the case of the bike sharing programs in Paris (Velib') and Barcelona (Bicing) can one identify a particular measure that appears to have been most important. Even in Paris and Barcelona, however, several other pro-bicycle interventions were undertaken before and during the bicycle sharing program, including expansion of the bikeway system and bike parking, bicycling education, and traffic calming. Congestion charging in central London (assessing a daily fee for entering a 21-sq.km zone) has been widely credited for increased bicycling there, but it is only one of many programs listed in Table 5 that have encouraged more bicycling since 2000 (Transport for London, 2008a,b).

Discussion

This review summarizes the available evidence on the impacts of a wide variety of bicycling interventions around the world. Most of the studies we surveyed suggest positive impacts of such interventions on bicycling levels. As noted by Ogilvie et al. (2004) in their review of pedestrian and bicycle interventions, “It is difficult to change long-standing and complex patterns of behavior so the evidence that some in-depth, targeted interventions have achieved any measurable shift is encouraging.” Moreover, the lack of evidence of a positive effect of some specific interventions is not the same as evidence of a lack of positive effect.

Our review reveals considerable variation in estimated impacts, both by type of intervention and by study design, location, and timing. That makes it difficult to generalize about the effectiveness of individual interventions or of bicycle interventions as a whole. Moreover, measures of bicycling (e.g., number of cyclists, number of bicycle trips, share of trips by bicycle, etc.) are not consistent across studies, making comparisons of estimated impacts difficult. Complicating matters further, some studies do not adequately explain their measures and methods, so it is difficult to assess whether variations across studies are simply an artifact of different methods used rather than a true difference in impacts. Non-peer-reviewed studies conducted by government agencies on their own interventions or by non-governmental organizations that advocate for bicycling policies may raise concerns about potential bias in the reporting of results.

The crucial limitation, however, is that most studies fall far short of the ideal research design for evaluating interventions, involving before-and-after measurements of a “treatment” and a “control” group (Krizek et al., 2009). As a result, these studies do not adequately address the direction of causality, such as whether bicycling infrastructure led to increased levels of bicycling or whether bicycling demand led to investments in bicycle infrastructure. Without an experimental design, it is difficult or impossible to control for other relevant factors such as cost and convenience of car use, income levels, urban form, and other factors that might be more important in affecting bicycling levels than explicitly pro-bicycle policies. In addition, many of the studies we have cited come from the “gray literature” and have not undergone a peer-review process that would provide some assurance of their rigor. Due to these many limitations, the empirical results summarized in this review should be viewed with caution.

Several factors probably moderate the effects of bicycling interventions. For example, land use planning in northern Europe is regionally coordinated and generally restricts low-density, car-oriented sprawl (Schmidt and Buehler, 2007). By promoting compact, mixed-use development, European land use policies generate shorter trip distances, which are more readily covered by bicycle. Restrictions on car use also affect bicycling. The much higher cost of car ownership and use in northern Europe encourages bicycling, especially combined with limited car parking, car-free zones, comprehensive traffic calming, and lower overall speed limits, which reduce the overall convenience and attractiveness of car use (Pucher and Buehler, 2008). The lack of such car-restrictive policies in the US probably reduces the impacts of policy interventions to increase bicycling.

The current level of bicycling in a community also affects bicycling safety and the potential to further increase bicycling. Several studies have demonstrated the principle of “safety in numbers.” Using both time-series and cross-sectional data, the studies find that bicycling safety is greater in countries and cities with higher levels of bicycling, and that bicycling injury rates fall as levels of bicycling increase. As the number of cyclists grows, they become more visible to motorists, which is a crucial factor in bicycling safety. In addition, a higher percentage of motorists are likely to be bicyclists themselves, and thus more sensitive to the needs and rights of bicyclists. The presence of large numbers of bicyclists may also help underpin their legal use of roadways and intersection crossings and generate public and political support for more investment in bicycling infrastructure (Elvik, 2009; Jacobsen, 2003; Robinson, 2005).

Culture, custom, and habit tend to foster bicycling in cities with high levels of bicycling but deter bicycling—especially among non-cyclists—in cities with low levels of bicycling, where it is viewed as a fringe mode (Pucher et al., 1999; de Bruijn et al., 2009). Non-cyclists in bicycle-oriented cities may respond differently to policy interventions than non-cyclists in cities with little bicycling. Research has found that non-cyclists who are surrounded by other cyclists may be more likely to have contemplated cycling and thus more responsive to policy interventions (Gatersleben and Appleton, 2007). Thus, the very same infrastructure provision, program, or policy might have different impacts on bicycling in different contexts, making it risky to generalize about the effectiveness of any individual measure.

In addition, there are important limitations to the evidence provided in the studies we surveyed that may mask the full effects of any particular intervention. The small estimated impacts of some of the specific infrastructure improvements examined in this review should not be misinterpreted as justification for not undertaking incremental steps toward a full system. Infrastructure measures are
almost always implemented in stages, not all at once. Many studies we examined only measured the impacts of incremental expansions and did not capture the full impact of a completed system. That might account for the small estimated impacts of some specific infrastructure improvements. A complete system of bicycling infrastructure (e.g., lanes, paths, cycletracks, bike boxes, traffic signals, parking, etc.) may have far more impact than the sum of its individual parts. Similarly, some specific programs might appear to have negligible impact when examined in isolation but significant impact when implemented comprehensively. Even more important, a coordinated package of complementary infrastructure measures, programs, and policies may enhance the impact of any intervention that is a component of that package.

Indeed, the most compelling evidence we found came from communities that have implemented a fully integrated package of strategies to increase bicycling. The cases reviewed here suggest that a comprehensive approach produces a much greater impact on bicycling than individual measures that are not coordinated. The impact of any particular measure is enhanced by the synergies with complementary measures in the same package. In that sense, the whole package is more than the sum of its parts. However, the more successfully a city implements a wide range of policies and programs simultaneously and fully integrates them with each other, the more difficult it becomes to disentangle the separate impacts of each measure. Both the apparent success of the comprehensive approach and the complexity of dissecting its effects point to a need for a meta-level approach to evaluation that examines the impacts of different sets of strategies across a large number of cases, taking into consideration the potential moderating factors in each of the cases examined, rather than a focus on the impacts of specific interventions in isolation.

It is also important to note the small number of studies, whether peer-reviewed or from the gray literature, for many of the interventions we examined. The vast majority of interventions do not include an evaluation component that would provide evidence of the impact of the intervention on the amount of bicycling. Public agencies and other organizations implementing interventions should collect before-and-after data on bicycling to facilitate the analysis of effectiveness. The development of standardized instruments to measure bicycling (e.g., household survey instruments, or protocols for bicycling counts) would facilitate data collection for resource-strapped agencies and organizations. Ideally, these groups should work with academic researchers in designing and carrying out the evaluation, including data collection and analysis, and would publish the results through the peer-review process. Research funding targeted at evaluating interventions through such partnerships would help to build a reliable and valid evidence base.

Despite all these caveats and the pressing need for additional research, a clear message emerges from our review: Some individual interventions can increase bicycling to varying degrees, but the increases are not usually large. That does not mean that individual interventions are not important, but they are most effective as a part of a more comprehensive effort. Substantial increases in bicycling require an integrated package of many different, complementary interventions, including infrastructure provision and pro-bicycle programs, as well as supportive land use planning and restrictions on car use.

There are many role models for cities to follow, as suggested by Table 5. Indeed, Bogota became a cycling success story by importing Dutch bicycle planners and adopting many of the pro-bicycle measures found in the Netherlands. But it added its own particularly South American program of ciclovias. Cities with successful bicycling policies can be found in many countries, providing experience about the most appropriate package of policies for local conditions.

Virtually all the available evidence indicates that policies make an important difference: not only explicitly pro-bicycle policies but also transport policies in general, housing and land use policies, and car pricing and restraint policies. Designing the appropriate mix of policies for each city’s particular situation requires careful planning and ongoing citizen input, especially from bicyclists. Emphasizing the proven health benefits of bicycling will be key to garnering the public and political support necessary to implement a truly comprehensive package of policies. That multifaceted, coordinated approach offers the promise of substantial growth in bicycling, even in cities with low bicycling levels.

Conflict of interest statement
All authors declare that they have no conflict of interest.

Acknowledgments
The authors would like to thank Lisa Dewey-Mattia and Mallory Atkinson, who assisted in gathering materials for the review, and Emmanuelle de Lanversin, Rose Ades, and Bernhard Gutzmer for contributing information on the case studies of Paris, London, and Freiburg. Jan Garrard, Jim Sallis, Nick Cavill, Ralph Buehler, Andrew Dannenberg, Michael Pratt, Peter Jacobsen, Olga Sarmiento, and four anonymous referees provided extensive feedback on earlier drafts that greatly improved the final version. This review was financed by a grant from the Active Living Research program of the Robert Wood Johnson Foundation.
